COVID-19 and complicated bacterial pneumonia in children

Mohamad Kaddour, Marcelle Simeonovic, Joshua Osowicki, Sarah McNab, Catherine Satzke, Colin Robertson, Cattram Nguyen, Sebastian King, Shivanthan Shanthikumar

This manuscript has recently been accepted for publication in the ERJ Open Research. It is published here in its accepted form prior to copyediting and typesetting by our production team. After these production processes are complete and the authors have approved the resulting proofs, the article will move to the latest issue of the ERJOR online.

COVID-19 AND COMPLICATED BACTERIAL PNEUMONIA IN CHILDREN

To the Editor,

We read with great interest the recent publication by Steinfort et al [1] outlining the profound reduction in influenza infections in Australia as a result of social distancing during the COVID-19 pandemic. Similar dramatic effects of social distancing on paediatric hospital activity have been reported, with reduced hospital admissions, presentations for respiratory conditions, and detection of other viruses.[2-6]

However, the impact of the pandemic on bacterial respiratory infections has not been well characterised. The Australian state of Victoria (population 6.7 million) has experienced a prolonged period of social restrictions (‘lockdown’) since March 2020. This period spanned the Southern Hemisphere Autumn to Spring, the usual peak period for bacterial respiratory infections.

Here, we assessed admissions to The Royal Children’s Hospital Melbourne (RCH) for thoracic empyema (‘empyema’), a complication of bacterial pneumonia that requires inpatient management. For added context, admissions for bronchiolitis, a common and well-defined viral respiratory infection, and
appendicitis, a common hospital-managed condition unlikely to be impacted by the lockdown, were assessed. RCH is the largest tertiary paediatric hospital in Victoria, with more than 89,000 emergency department presentations and 52,000 inpatient admissions annually.

Admissions from March to August 2020 were compared with the same months in the preceding three years. Patients with empyema aged 0-18 years were identified by ICD-10 discharge diagnosis. Every case was validated by manual file review using the electronic medical record, and incorrectly coded cases were excluded (26/113, 23.0%). Discharge coding for bronchiolitis (0-12 months) and appendicitis (0-18 years) was validated for a subgroup of patients and found to be greater than 95% accurate. For each condition, Poisson regression was used to compare the number of admissions across the study years. The only covariate in the models was year of admission, which was treated as a categorical variable, with 2020 as the reference category. Analyses were performed using Stata version 16.1. The RCH Human Research Ethics Committee approved the study (HREC/65077/RCHM-2020).

During lockdown, we observed a significant reduction in the cases of empyema (figure 1). A comparable reduction was seen for bronchiolitis but not for appendicitis, suggesting that our findings were unlikely to be due to changes in hospital presentation. These findings match the large reductions in influenza, respiratory syncytial virus, bronchiolitis, and viral pneumonia cases reported by others during pandemic-related lockdown.[1, 6, 8] Elsewhere, a decline in streptococcal pharyngitis, acute otitis media and infectious mononucleosis has been noted.[4] Together, these data suggest a significant reduction in viral and bacterial respiratory tract infections. The Northern Hemisphere is now approaching its usual peak season for respiratory infection. Further studies may determine the extent to which the reduction in empyema that we observed may be attributed to decreased bacterial transmission or a decisive role for viral infection in the pathogenesis of complicated bacterial pneumonia.
Figure Caption

Figure 1A. Bar chart of bronchiolitis, empyema and appendicitis admissions occurring between March and August, 2017-2020. 1B. Results from Poisson regression models comparing the number of bronchiolitis, empyema and appendicitis admissions between March and August, 2017-2020.

Take-Home Message

Social distancing measures instituted due to #SARSCoV2 have dramatically reduced paediatric thoracic empyema cases in Australia
Declaration of Interests

The authors have no relevant interests to declare. CN and CS have received grants from Pzifer unrelated to this work.
